

# Abstract

In a previous study we examined the rates of births in the U.S. and found a possible, weak correlation with the phase of the Moon, with a peak occurring near third quarter (BAAS 26, No. 4, 1994). That study used data on about 45 million births over 12 years. In this extension of that work we have added data from eight more years of births. We present the results of the new analysis of the extended data base.
